NP-Hard problems and SDP

- Solving hard combinatorial/discrete optimization problems requires: efficient upper/lower bounding techniques.
- These problems are often modelled using quadratic objectives and/or quadratic constraints, i.e., QQPs.
- Lagrangian relaxations of QQPs lead to Semidefinite Programming, SDP, and SDP relaxations, e.g., Handbooks on SDP and Cone Optimization; [25, 1].

Solving Large Scale Problems; Reductions

- SDP's (relaxations) are **expensive** to solve using the (early methods of choice) interior-point approaches. This becomes *doubly* expensive when cutting planes are added, e.g., using Doubly Nonnegative, **DNN**, relaxations; i.e., these methods **do not scale well** and generally do **NOT** provide **high accuracy solutions**.
- There are currently few techniques that: exploit structure; reduce size of data; **and** handle large scale problems:
 - chordality reduction
 - facial reduction and regularization, FR
 - symmetry reduction, SR
 - **first order methods** (splittings, e.g., ADMM)

Facial Reduction, FR ; and Symmetry Reduction, SR

- Strict feasibility (regularity) fails for many of the SDP relaxations of many hard combinatorial problems. (Compare Rademacher Theorem: Loc. Lip. functions are differentiable a.e.)
FR, e.g., [2, 3, 4, 9, 19] provides a means of regularizing the SDP relaxations, while simultaneously reducing the size.
- **SR** e.g., Schrijver [20]; [19, 23, 6, 10, 11], is used to obtain a (simplified) block diagonal form, for problems that are **invariant under the action of a symmetry group**. Essentially, the problem can be restricted to a **matrix *-algebra** that contains the data matrices. Then a rotation results in the **block diagonal simplified, smaller**, reduced, structure.

FR and SR **together** into ADMM to Solve **Humongous** Problems

- **FR, SR** appear to provide a **regularization** and **natural splitting of variables** for the application of Alternating Direction Method of Multipliers, **ADMM**, type methods for large scale problems;
and for exploiting structure.
- Classes of Problems:
Min-Cut; Maxcut; Graph Partitioning; Vertex Separator;
and here: Quadratic Assignment Problem, **QAP**

What is the QAP?

$A, B \in \mathbb{S}^n$ real symmetric $n \times n$ matrices, C real $n \times n$,
 $\langle \cdot, \cdot \rangle$ denotes **trace inner product**, $\langle Y, X \rangle = \text{trace } YX^T$,
and Π_n **set of $n \times n$ permutation matrices** (permutations ϕ)

assign n facilities to n locations; minimize total cost

flow is A_{ij} between facilities i, j and it multiplies
distance $B_{\phi(i)\phi(j)}$ to get the total cost of assigning facilities i, j
to locations $\phi(i), \phi(j)$, respectively;
then add **location costs** in $-\frac{1}{2} (C_{i\phi(i)} + C_{j\phi(j)})$

Discrete Optimization Model

The **quadratic assignment problem, QAP**, in the trace formulation

$$\text{(QAP)} \quad p^* := \min_{X \in \Pi_n} \langle AXB - 2C, X \rangle \quad \left(= \text{trace}(AXB - 2C)X^T \right)$$

Applications Include:

Koopmans-Beckmann '57 [14]; Nyberg et al '12 [17]

- facility location planning: Universities, hospital layout, airport gate assignment, **wiring problems/circuit boards/VLSI**, typewriter keyboards (though max?)
- Bandwidth minimization of a graph
- Image processing
- Scheduling
- Supply Chains
- Economics
- Molecular conformations in chemistry
- Manufacturing lines
- Includes as special case: Traveling salesman problem and Maximum cut problem

QQP: Quadratic-Quadratic Model for $X \in \Pi$

$Xe = e, X^T e = e, X \geq 0$, doubly stochastic; (e – ones vector)
turn linear constraints into quadratic

Start with Quadratic-Quadratic Model for $X \in \Pi$, a QQP

$$\begin{aligned} \min_X \quad & \langle AXB - 2C, X \rangle \\ \text{s.t.} \quad & \|Xe - e\|^2 + \|X^T e - e\|^2 = 0 && \text{(r-c sums)} \\ & XX^T = X^T X = I_n && \text{(orthogonality)} \\ & X_{ij}X_{ik} = 0, X_{ij}X_{ki} = 0, \forall i, \forall j \neq k, && \text{(gangster)} \\ & X_{ij}^2 - X_{ij} = 0, \forall i, j, && \text{(0-1)} \\ & X \geq 0 && \text{(nonnegativity)} \end{aligned}$$

Dual of Dual is SDP Relaxation

The Lagrangian dual is an SDP.

The (Lagrangian) dual of this SDP is equivalent to the SDP relaxation of the QQP. **BUT**, strict feasibility (Slater) fails!

Start new derivation; QQP with fewer constraints; OWX [18] '18

$$\begin{aligned}
 \min_X \quad & \langle AXB - 2C, X \rangle \\
 \text{s.t.} \quad & X_{ij}X_{ik} = 0, X_{ji}X_{ki} = 0, \forall i, \forall j \neq k, && \text{(gangster)} \\
 & X_{ij}^2 - X_{ij} = 0, \forall i, j, && \text{(0 - 1)} \\
 & \sum_{i=1}^n X_{ij}^2 - 1 = 0, \forall j, \sum_{j=1}^n X_{ij}^2 - 1 = 0, \forall i. && \text{(r-c sums)}
 \end{aligned}$$

linearization/lifting to $Y \in \mathbb{S}^{n^2+1}$: $Y_{(ij)(st)} \cong X_{ij}X_{st}$

Gangster constraints

- The first set of constraints, the elementwise orthogonality of the row and columns of X , are the **gangster constraints**. They are particularly strong constraints and enable many of the other constraints (such as orthogonality $XX^T = I, X^T X = I$, row and columns sums are 1) to be redundant.
- In fact, after the facial reduction, FR, many of these constraints also become redundant.

Lifting; blocked appropriately; $x = \text{vec}(X)$ columnwise

$$Y = \begin{pmatrix} x_0 \\ x \end{pmatrix} \begin{pmatrix} x_0 \\ x \end{pmatrix}^T =: \begin{bmatrix} Y_{00} & Y_{01:n^2} \\ Y_{1:n^2 0} & \bar{Y} \end{bmatrix} \in \mathbb{S}^{n^2+1},$$

$$Y_{1:n^2 0} := \begin{bmatrix} Y_{(10)} \\ Y_{(20)} \\ \vdots \\ Y_{(n^2,0)} \end{bmatrix}; \quad \bar{Y} := \begin{bmatrix} \bar{Y}_{(11)} & \bar{Y}_{(12)} & \cdots & \bar{Y}_{(1n)} \\ \bar{Y}_{(21)} & \bar{Y}_{(22)} & \cdots & \bar{Y}_{(2n)} \\ \vdots & \ddots & \ddots & \vdots \\ \bar{Y}_{(n1)} & \ddots & \ddots & \bar{Y}_{(nn)} \end{bmatrix}$$

Objective

$$\text{trace } AXBX^T = \text{trace } L_A Y, \text{ where } L_A := \begin{bmatrix} 0 & 0 \\ 0 & B \otimes A \end{bmatrix}.$$

where \otimes is Kronecker product

SDP Constraints (after the lifting/linearization)

E.g., the arrow constraint (linearization from the 0, 1 constraint)

$$\text{arrow}(Y) := \text{diag}(Y) - \begin{bmatrix} 0 \\ Y_{1:n^2} 0 \end{bmatrix} = e_0,$$

e_0 first (0-th) unit vector
(redundant in the final SDP relaxation)

DNN, doubly nonnegative

$$Y \in \text{DNN} = \{Y \in \mathbb{S}_+^{n^2+1} : 0 \leq Y (\leq 1)\}$$

DNN is doubly nonnegative cone, i.e., intersection of positive semidefinite cone and nonnegative orthant.

Trace constraints (from linear equality constraints)

$$\text{trace } D_1 Y = 0, \quad D_1 := \begin{bmatrix} n & -e_n^T \otimes e_n^T \\ -e_n \otimes e_n & (e_n e_n^T) \otimes I_n \end{bmatrix},$$

$$\text{trace } D_2 Y = 0, \quad D_2 := \begin{bmatrix} e^T e & -e^T \otimes e_n^T \\ -e \otimes e_n & I_n \otimes (e_n e_n^T) \end{bmatrix},$$

e_j vector of ones of dimension j ; $D_i \succeq 0, i = 1, 2$; nullspaces of these matrices yield the facial reduction $Y = VRV^T$.

Block: trace, diagonal and off-diagonal

$$\begin{aligned} \mathcal{D}_t(Y) &:= \left(\text{trace } \bar{Y}_{(ij)} \right) = I \in \mathbb{S}^n; \\ \mathcal{D}_d(Y) &:= \sum_{i=1}^n \text{diag } \bar{Y}_{(ij)} = e_n \in \mathbb{R}^n; \\ \mathcal{D}_o(Y) &:= \left(\sum_{s \neq t} \left(\bar{Y}_{(ij)} \right)_{st} \right) = \hat{l} \in \mathbb{S}^n, \end{aligned}$$

where $\hat{l} := ee^T - I$.

trace $Y = n + 1$; and Gangster constraints on Y

The Hadamard product and orthogonal type constraints lead to **gangster constraints**

i.e., simple constraints that restrict elements to be zero (shoot holes in the matrix) and/or restrict entire blocks.

gangster and restricted gangster constraint on Y :

$$\mathcal{G}_H(Y) = 0,$$

for specific index sets H , e.g., Hadamard orthogonal rows of $X \in \Pi$ yields

$$i \neq j : \implies X_{ik} X_{jk} = 0, \forall k \implies Y_{(ik),(jk)} = 0, \forall k.$$

SDP Relaxation with Many (some redundant) Constraints

$$\begin{aligned}
 \text{qap}(n, A, B) \geq p_{\text{SDP}}^* &:= \min && \text{trace } L_A Y \\
 &\text{s.t.} && \text{arrow}(Y) = e_0 \\
 &&& \text{trace } D_1 Y = 0, \text{ trace } D_2 Y = 0 \\
 &&& \mathcal{G}_{J_0}(Y) = 0, Y_{00} = 1 \\
 &&& \mathcal{D}_t(Y) = I, \mathcal{D}_d(Y) = e, \mathcal{D}_o(Y) = \hat{I} \\
 &&& Y \in \mathbb{S}_+^{n^2+1}
 \end{aligned}$$

Equivalent FR greatly simplified SDP; with $Y = \tilde{V}R\tilde{V}^T$

$$\begin{aligned}
 \text{qap}(n, A, B) \geq p_{\text{SDP}}^* &= \min && \text{trace} \left(\tilde{V}^T L_A \tilde{V} \right) R \\
 &\text{s.t.} && \mathcal{G}_{J_I}(\tilde{V}R\tilde{V}^T) = \mathcal{G}_{J_I}(e_0 e_0^T) \\
 &&& R \in \mathbb{S}_+^{(n-1)^2+1}
 \end{aligned}$$

Natural Splitting? $Y \in \mathcal{P}, R \in \mathbb{S}_+^r$

$$Y = VRV^T$$

$$Y \in \mathcal{P} \subset \mathbb{S}_+^{N+1}, \quad R \in \mathbb{S}_+^r, \quad r < N + 1$$

Facial reduction provides a **guarantee** that **strict feasibility** holds for the **primal** and that the **dual of the dual** is the primal. (In our instance of QAP, strict feasibility holds for primal and dual.)

AND: it provides a **reduction in dimension AND so rank**.

Natural separation/splitting

There is a natural separation of constraints where

$$Y \in \mathcal{P} \text{ polyhedral} \quad R \in \mathbb{S}_+^r \text{ sdp cone}$$

General primal-dual SDP

$$p_{\text{SDP}}^* = \min\{\langle C, X \rangle \mid \mathcal{A}(X) = b \in \mathbb{R}^m, X \in \mathbb{S}_+^n\},$$

where $A_j \in \mathbb{S}^n$, $\mathcal{A}(X) = (\text{trace } A_j X)$

$$d_{\text{SDP}}^* = \max\{\langle b, y \rangle \mid \mathcal{A}^*(y) \preceq C, y \in \mathbb{R}^m\}$$

where \mathcal{A}^* is the **adjoint** of \mathcal{A} ; $\mathcal{A}^*(y) = \sum_i y_i A_i$.

SR: substitute using \tilde{B}^* ; obtain SR block diagonal form

- use procedure for simplifying an SDP that is invariant under the action of a symmetry group, Schrijver [20];
- the appropriate algebra isomorphism follows from the Artin-Wedderburn theory [24].

Framework

- \mathcal{G} - nontrivial **group of permutation matrices** of size n .
- **commutant**, $A_{\mathcal{G}}$ (or centralizer ring) of \mathcal{G} :

$$\begin{aligned} A_{\mathcal{G}} &= \{X \in \mathbb{R}^{n \times n} \mid PX = XP, \forall P \in \mathcal{G}\} \\ &= \{X \in \mathbb{R}^{n \times n} \mid \mathcal{R}_{\mathcal{G}}(X) = X\}, \end{aligned}$$

where $\mathcal{R}_{\mathcal{G}}(X) := \frac{1}{|\mathcal{G}|} \sum_{P \in \mathcal{G}} PXP^T$, is the **Reynolds operator**, or group average, and is **orthogonal projection onto the commutant**;

- the commutant $A_{\mathcal{G}}$ is a **matrix *-algebra**, i.e., closed under addition, scalar multiplication, matrix multiplication, and taking transposition.

Basis for A_G : $\{B_1, \dots, B_d\}$, $B_i \in \{0, 1\}^{n \times n}$

- **basis for A_G** from the orbits of the action of \mathcal{G} on ordered pairs of vertices, where the orbit of $(u_i, u_j) \in \{0, 1\}^n \times \{0, 1\}^n$ under the action of \mathcal{G} is the set $\{(Pu_i, Pu_j) \mid P \in \mathcal{G}\}$, and $u_i \in \mathbb{R}^n$ is the i -th unit vector.

Definition (coherent configuration (J ones matrix))

A set of zero-one $n \times n$ matrices $\{B_1, \dots, B_d\}$ is called a **coherent configuration of rank d** if

- 1 $\sum_{i \in \mathcal{I}} B_i = I$ for some $\mathcal{I} \subset \{1, \dots, d\}$, and $\sum_{i=1}^d B_i = J$;
- 2 $B_i^T \in \{B_1, \dots, B_d\}$ for $i = 1, \dots, d$;
- 3 $B_i B_j \in \text{span}\{B_1, \dots, B_d\}$, $\forall i, j \in \{1, \dots, d\}$.

Theorem (de Klerk et al, [7])

Let A_G denote a *matrix $*$ -algebra* that *contains the data matrices* of an SDP problem as well as the identity matrix. If the SDP problem *has an optimal solution*, then it *has an optimal solution in A_G* , the centralizer ring.

Corollary (can reduce size of feasible set to consider)

We can *restrict the feasible set* of the optimization problem to its *intersection with A_G* . In particular, we can use the basis matrices and assume that

$$X \in \mathcal{F}_X \cap A_G \Leftrightarrow \left[X = \sum_{i=1}^d x_i B_i =: \mathcal{B}^*(x) \in \mathcal{F}_X, \text{ for some } x \in \mathbb{R}^d \right].$$

First SR using substitution $X = \mathcal{B}^*(x)$

We assume that the group of permutation matrices \mathcal{G} is such (small enough) that the centralizer/commutant $A_{\mathcal{G}}$ contains our data matrices, (A_i, C) .

$$\rho_{\text{SDP}}^* = \min\{\langle C, X \rangle \mid \mathcal{A}(X) = b, X \succeq 0\}$$

Feasible set reduced; optimal value unchanged

$$\rho_{\text{SDP}}^* = \min\{\langle \mathcal{B}(C), x \rangle \mid (\mathcal{A} \circ \mathcal{B}^*)(x) = b, \mathcal{B}^*(x) \succeq 0\}$$

Here, $\mathcal{B} = \mathcal{B}^{**}$ is the **adjoint** of \mathcal{B}^* .

In the case of a doubly nonnegative relaxation, the structure of our basis allows us to set/constrain $x \geq 0$.

Basic *-algebra

\mathcal{M} is called basic if $\mathcal{M} = \{\oplus_{i=1}^t M \mid M \in \mathbb{C}^{m \times m}\}$, where \oplus denotes the direct sum of matrices.

Theorem (Wedderburn [24])

*Let \mathcal{M} be a matrix *-algebra containing the identity matrix. Then there exists a unitary matrix Q such that $Q^* \mathcal{M} Q$ is a direct sum of basic matrix *-algebras.*

Mutual block diagonalization with orthogonal Q , t blocks

$$\tilde{B}_j := Q^T B_j Q =: \text{Blkdiag}((\tilde{B}_j^k)_{k=1}^t), \forall j = 1, \dots, d.$$

Linear transformation for $Q^T X Q = \sum_{j=1}^d x_j \tilde{B}_j =: \tilde{B}^*(x)$

$$\sum_{j=1}^d x_j \tilde{B}_j = \begin{bmatrix} \tilde{B}_1^*(x) & & \\ & \ddots & \\ & & \tilde{B}_t^*(x) \end{bmatrix} =: \text{Blkdiag}((\tilde{B}_k^*(x))_{k=1}^t)$$

where $\tilde{B}_k^*(x) =: \sum_{j=1}^d x_j \tilde{B}_j^k \in \mathcal{S}_+^{n_i}$ is k -th diagonal block of $\tilde{B}^*(x)$, and sum of t block sizes $n_1 + \dots + n_t = n$.

For any feasible X

$$X = \mathcal{B}^*(x) = Q \tilde{B}^*(x) Q^T \in \mathcal{F}_X$$

Second SR block diagonal form using $X = Q\tilde{B}^*(x)Q^T$

Block diagonal problem

$$p_{\text{SDP}}^* = \min\{\langle \tilde{B}(\tilde{C}), x \rangle \mid (\tilde{A} \circ \tilde{B}^*)(x) = b, \tilde{B}^*(x) \succeq 0\},$$

After appropriate simplifications

$$p_{\text{SDP}}^* = \min\{c^T x \mid Ax = b, \tilde{B}_k^*(x) \succeq 0, k = 1, \dots, t\}.$$

feasible set and feasible slacks are

$$\mathcal{F}_x := \{x \mid \tilde{B}^*(x) \succeq 0, Ax = b, x \in \mathbb{R}^d\}$$

$$\mathcal{S}_x := \{\tilde{B}^*(x) \succeq 0 \mid Ax = b, x \in \mathbb{R}^d\}.$$

$\tilde{B}^*(x)$ is a block-diagonal matrix

get smaller problem typically: $x \in \mathbb{R}^d$, $d \ll \sum_{i=1}^d t(n_i) \ll t(n)$,
where $t(k) = k(k+1)/2$ is the triangular number.

Maximum rank preserving properties of SR

$$\begin{aligned} \max\{\text{rank}(X) : X \in \mathcal{F}_X\} &= \text{rank}(X), \forall X \in \text{ri}(\mathcal{F}_X) \\ &= \text{rank}(X), \forall X \in \text{ri}(\text{face}(\mathcal{F}_X)), \end{aligned}$$

$\text{face}(\mathcal{F}_X)$ is minimal face of \mathbb{S}_+^n containing feasible set.

Theorem

Let $r = \max\{\text{rank}(X) : X \in \mathcal{F}_X\}$. Then

$$\begin{aligned} r &= \max\left\{\text{rank}\left(\frac{1}{|\mathcal{G}|} \sum_{P \in \mathcal{G}} P^T X P\right) : X \in \mathcal{F}_X\right\} \\ &= \max\{\text{rank}(X) : X \in \mathcal{F}_X \cap \mathcal{A}_{\mathcal{G}}\} \text{ centralizer} \\ &= \max\{\text{rank}(\tilde{\mathcal{B}}^*(x)) : \tilde{\mathcal{B}}^*(x) \in \mathcal{S}_x\} \text{ slacks} \end{aligned}$$

FR; exposing vectors; symmetry reduced programs

For many combinatorial problems, the semidefinite relaxation is **not strictly feasible**. Therefore it is **degenerate and ill-posed**. Therefore, the **symmetry reduced problem is degenerate as well**.

We want to implement both SR and FR together and do it efficiently and robustly.

Key is exposing vectors

The exposing vectors **of symmetry reduced** program can be obtained from the exposing vectors **from original program**. (Therefore, we can exploit structure of original problem.)

Exposing vectors for FR

Let $0 \neq W = UU^T$ be an exposing vector of the minimal face of \mathbb{S}_+^n containing the feasible region \mathcal{F}_X :

$X \in \mathcal{F}_X \implies \text{trace } WX = 0$;

let $U \in \mathbb{R}^{n \times (n-r)}$ full column rank;

let $V \in \mathbb{R}^{n \times r}$ with $\text{Range}(V) = \text{Null}(U^T)$.

FR: use substitution $X = \mathcal{V}^*(R) = VRV^T$

obtain equivalent, smaller,

$$\min\{\langle V^T CV, R \rangle \mid \langle V^T A_i V, R \rangle = b_i, \quad i = 1, \dots, m, \quad R \in \mathbb{S}_+^r\}.$$

In fact, with appropriate V , \hat{R} strictly feasible corresponds to $\hat{X} = \mathcal{V}^*(\hat{R}) \in \text{ri}(\mathcal{F}_X)$. Moreover, at least one constraint becomes redundant at each FR step.

(So at most $\min\{m, n-1\}$ FR steps.)

Exposing vectors for SR in commutant A_G

Lemma

Let W be an exposing vector of rank d of a face of \mathbb{S}_+^n containing \mathcal{F}_X . Then there exists an exposing vector $W_G \in A_G$ with $\text{rank}(W_G) \geq d$.

Proof.

Let W be the exposing vector of rank d , i.e., $W \succeq 0$ and $X \in \mathcal{F}_X \implies \langle W, X \rangle = 0$.

Since the original problem is \mathcal{G} -invariant, $PXP^T \in \mathcal{F}_X$ for every $P \in \mathcal{G}$, we conclude that

$$\langle W, PXP^T \rangle = \langle P^T WP, X \rangle = 0.$$

Therefore, $P^T WP \succeq 0$ is an exposing vector of rank d . Thus $W_G = \frac{1}{|\mathcal{G}|} \sum_{P \in \mathcal{G}} P^T WP$ is an exposing vector of \mathcal{F}_X .

That the rank is at least d follows from taking the sum of nonsingular congruences of $W \succeq 0$. □

Lemma

Let W be an exposing vector of face of \mathbb{S}_+^n containing \mathcal{F}_X , and assume that $W \in A_G$. Let Q be the orthogonal matrix given above in the block diagonalization. Then $\widetilde{W} = Q^T W Q$ exposes a face of \mathbb{S}_+^n containing S_X .

Theorem

Let $W \in A_G$ be an exposing vector of $\text{face}(\mathcal{F}_X)$, the minimal face of \mathbb{S}_+^n containing \mathcal{F}_X . Then the block-diagonal matrix $\widetilde{W} = Q^T W Q$ exposes $\text{face}(S_X)$, the minimal face of \mathbb{S}_+^n containing S_X .

Facial and symmetry reduced program

$\tilde{W} = Q^T W Q$ exposes the minimal face of \mathbb{S}_+^n containing \mathcal{S}_x ;

$$\tilde{W} = \text{Blkdiag}(\tilde{W}_1, \dots, \tilde{W}_t), \quad \tilde{W}_i = \tilde{U}_i \tilde{U}_i^T, \quad \tilde{U}_i \text{ full rank}, \quad i = 1, \dots, t$$

Let \tilde{V}_i be a full rank matrix $\text{Range}(V_i) = \text{Null}(U_i^T)$

$$\tilde{V} = \text{Blkdiag}(\tilde{V}_1, \dots, \tilde{V}_t).$$

FR:

$$\begin{aligned} p_{FR}^* &= \min\{c^T x \mid Ax = b, \tilde{\mathcal{B}}^*(x) = \tilde{V} \tilde{R} \tilde{V}^T, \tilde{R} \succeq 0\} \\ &= \min\{c^T x \mid Ax = b, \tilde{\mathcal{B}}_k^*(x) = \tilde{V}_k \tilde{R}_k \tilde{V}_k^T, \tilde{R}_k \succeq 0, k = 1 : t\} \end{aligned}$$

where $\tilde{V}_k \tilde{R}_k \tilde{V}_k^T$ is the corresponding k -th block of $\tilde{\mathcal{B}}^*(x)$, and $\tilde{R} = \text{Blkdiag}(\tilde{R}_1, \dots, \tilde{R}_t)$.

Singularity degree for FR and SR

Definition

The singularity degree of a feasible region \mathcal{F} , denoted by $sd(\mathcal{F})$, is the smallest number of steps required for the FR algorithm to terminate.

Holder error bound, Sturm '00 [21]

For a feasible set $\mathcal{F}_X = \mathcal{L} \cap \mathbb{S}_+^n$, for a linear manifold \mathcal{L} , Sturm showed that a **Holder error bound** always holds, i.e., the distance of any X to \mathcal{F}_X can be bounded by a multiple of a certain power of the distance to \mathcal{L} and to \mathbb{S}_+^n separately. Sturm showed that the **Holder exponent** can be set to $2^{-sd(\mathcal{F}_X)}$. (It does **NOT** depend on the size or rank of the matrices, only the singularity degree.)

Theorem

$$sd(\mathcal{F}_x) \leq sd(\mathcal{F}_X).$$

Difficulties for primal-dual interior-point methods for SDP

- solving large problems
- obtaining high accuracy solutions
- exploiting sparsity
- adding on nonnegativity and other cutting plane constraints

First order operator splitting methods for SDP

- FR/SR: regularization/dim. size reduction/natural splitting,
 $Y = VRV^T$
- Flexibility in dealing with additional constraints
- separable/split optimization steps are inexpensive

It is extremely successful for splittings with two cones. The ADMM is well suited for large-scaled DNN problems, where one can split between simple polyhedral and convex cone projections, e.g., survey Boyd et al '11 [5]; applications to QAP, Mincut e.g., [18, 15, 12].

Augmented Lagrangian for: $\tilde{B}^*(x) = \tilde{V}\tilde{R}\tilde{V}^T$

Let $\tilde{V} = \text{Blkdiag}(\tilde{V}_1, \dots, \tilde{V}_t)$ and $\tilde{R} = \text{Blkdiag}(\tilde{R}_1, \dots, \tilde{R}_t)$.

The augmented Lagrangian

$$\mathcal{L}(x, \tilde{R}, \tilde{Z}) = \langle \tilde{C}, \tilde{B}^*(x) \rangle + \langle \tilde{Z}, \tilde{B}^*(x) - \tilde{V}\tilde{R}\tilde{V}^T \rangle + \frac{\beta}{2} \|\tilde{B}^*(x) - \tilde{V}\tilde{R}\tilde{V}^T\|^2$$

where, $\tilde{C} = Q^T C Q$ is block-diagonal matrix as $C \in A_G$;
Lagrange multiplier \tilde{Z} is also in block-diagonal form;
 $\beta > 0$ is the penalty parameter.

$$\max_{\tilde{Z}} \min_{x \in P, \tilde{R} \succeq 0} \mathcal{L}(x, \tilde{R}, \tilde{Z}),$$

P is a simple polyhedral set: $Ax = b, x \geq 0$

Splitting yields three subproblems

find following updates $(x_+, \tilde{R}_+, \tilde{Z}_+)$:

$$x_+ = \arg \min_{x \in P} \mathcal{L}(x, \tilde{R}, \tilde{Z}),$$

$$\tilde{R}_+ = \arg \min_{\tilde{R} \succeq 0} \mathcal{L}(x_+, \tilde{R}, \tilde{Z}),$$

$$\tilde{Z}_+ = \tilde{Z} + \gamma\beta(\tilde{\mathcal{B}}^*(x_+) - \tilde{V}\tilde{R}_+\tilde{V}^T).$$

$\gamma \in (0, \frac{1+\sqrt{5}}{2})$ - step size for updating dual variable \tilde{Z} .

Complete square

$$\begin{aligned}\tilde{R}_+ &= \min_{\tilde{R} \succeq 0} \|\tilde{\beta}^*(x) - \tilde{V}\tilde{R}\tilde{V}^T + \frac{1}{\beta}\tilde{Z}\|^2 \\ &= \min_{\tilde{R} \succeq 0} \|\tilde{R} - \tilde{V}^T(\tilde{\beta}^*(x) + \frac{1}{\beta}\tilde{Z})\tilde{V}\|^2 \\ &= \sum_{k=1}^t \min_{\tilde{R}_k \succeq 0} \|\tilde{R}_k - (\tilde{V}^T(\tilde{\beta}^*(x) + \frac{1}{\beta}\tilde{Z})\tilde{V})_k\|^2.\end{aligned}$$

Solve k small problems/psd projections

$$\tilde{R}_k = \mathcal{P}_{\mathbb{S}_+} \left(\tilde{V}^T(\tilde{\beta}^*(x) + \frac{1}{\beta}\tilde{Z})\tilde{V} \right)_k, \quad k = 1, \dots, t,$$

On solving the x -subproblem

$$x_+ = \arg \min_{x \in P} \left\| \tilde{B}^*(x) - \tilde{V} \tilde{R} \tilde{V}^T + \frac{\tilde{C} + \tilde{Z}}{\beta} \right\|^2.$$

- For many combinatorial optimization problems, some of the constraints such as in $Ax = b$ become redundant after FR of their semidefinite programming relaxations.
- Thus, the set P often collapses to a simple set. This often leads to an analytic solution for the x -subproblem.
- This happens for the quadratic assignment, graph partitioning, vertex separator, and shortest path problems.

Tests using:

- computer: DellPowerEdge; two Intel Xeon E5-2637v3 4-core 3.5 GHz (Haswell) processors; 64GB of memory
- Mosek as the interior point solver
- We include *huge* problems of sizes up to $n = 512$, i.e. the SDP relaxation is of size $n^2 + 1 = 1 + 512^2$ and this therefore includes order $n^4 = 625 * 10^8$ nonnegativity constraints.

Stopping

We terminate when the primal and dual residuals are small or we are not making progress in decreasing the duality gap.

Significant improvements for huge problems

- The following table shows that we significantly improve bounds for all eng1_ n and eng9_ n instances.
- Moreover, we are able to compute bounds for huge QAP instances with $n = 256$ and $n = 512$ in a reasonable amount of time.
- Note that for each instance from of size $n = 2^d$, the DNN relaxation boils down to $d + 1$ positive semidefinite blocks of order n . There are currently no interior point algorithms that are able to solve such huge problems.

Mittlemann and Peng problems '10 [16]

Table: Lower and upper bounds for different QAP instances.

Table: Esc instances

- We discussed strategies for finding new, strengthened lower and upper bounds, for large discrete optimization problems from the resulting HUGE DNN relaxations.
- In particular, we combined FR with SR efficiently to obtain a regularized problem reduced in dimension and in size. We exploited the resulting **natural splitting** with a **ADMM** approach.
- Interesting theoretical results about singularity degree and rank preservation arose for the SR.
